Observable Prefix Transfer Evidence Sheet

Result, 8 November 2026. The primary error-discrimination question remains unidentified by class support. This pilot evaluates probability scores on a selected, mostly correct population; it does not establish an error detector, equivalence to no effect, universal reasoning states or useful stopping.

Question. Do ordered features of observable reasoning prefixes add correctness information beyond task attributes, surface text, lexical dynamics and pooled content when both the target model and test-task roots are excluded from fitting?

Actual sample. DeepSeek-V4.1-Flash and GPT-OSS-20B produced 384 saved main attempts on 96 tasks/48 paired roots in four programmed domains: 335 completed traces, 49 output-limit exclusions and 333 gradeable answers, including 329 correct and four incorrect. Qwen3-32B failed finite admission; its 192 main cells remain unsent. Both semantic embedders cover all 5,778 chunks. See coverage and the paper.

Primary BGE-M3 / 256 words	Test traces / roots	Static-minus-dynamic log-loss gain [pointwise 95% interval]	Interpretation
DeepSeek held out	20 / 9	-0.00154 [-0.00669, 0.00290]	Target has no errors; error-ranking AUROC undefined
GPT-OSS held out	34 / 11	0.00000 [0.00000, 0.00000]	Source has no errors; identical constant predictors force zero

Controls and limits. Source-only transforms and validation tuning precede target evaluation. Direct refitted reverse/three-shuffle comparisons preserve content; all primary BGE DeepSeek log-loss intervals span zero. Intervals condition on fitted predictors and observed roots, without training uncertainty or multiplicity correction. Qwen's secondary 256-word DeepSeek gain is -0.00259 [-0.00700, 0.00138]. All secondary results are retained. E0 remains unpassed. New task instances are not new mechanisms, and model holdout is not automatically independent family holdout.

Research judgment and implementation evidence. Separate deterministic checks support all four error labels; two formatting failures retain unavailable labels. Operational amendments after API preflight preserve original source/protocol bytes, raw IDs, rejected routing batches and one ledger, while pinning later embedding requests to DeepInfra without fallback. Matched-embedder refits reproduce original predictions. Source/plan, error certificates and claims map make these decisions inspectable. Mechanical tests and replay do not supply human scientific review.

Cost. New API-reported charges total 22.26254 RUB. Conservative new charged-or-reserved obligations are 404.71915 RUB, including 4.17591 RUB without reported cost. Including 246.79888 RUB historical obligations gives 651.51803 RUB against the authorized 3000 RUB ceiling. **651.52 RUB is not measured spending.** Accounting retains charges, reservation margin and unknown-cost commitments separately.

Free replay. With `requirements-resumption.txt` installed, run `scripts/reproduce_local.py --manifest evidence/local-pilot-2026-11-08/manifest.json --output .research/local-replay-check` using Python. It verifies/restores the bundle and reruns frozen analysis without API calls; the output directory must be new.

Contribution and next evidence. The owner set the objective, recorded design choices and authorized execution. Codex and programming assistants performed substantial code, tests, source review, analysis preparation and drafting. These are AI-assisted checks, not independent human scientific review or unaided human execution. A stronger study needs fresh tasks yielding sufficient completed errors at prospective prefixes, followed by new held-out evaluation. Personal application drafts and actual involvement belong to the owner, consistent with Anthropic candidate AI guidance. No application or article is submitted.
